ABSTRACT

Difficulties associated with the DACUM (Developing a Curriculum) process of the British Columbia Ministry of Education were identified in this study. Using a task analysis of a hunter's job, a set of procedures was developed that can improve the curriculum development process and, to some extent, overcome the difficulties associated with it. The study used a collection of task statements generated in a workshop setting, distributed them to the field for responses, and then clustered these task statements on the basis of field responses. The clusters were then examined according to a behavioral taxonomy. This process allows for the identification of the physical and psychological requirements associated with a cluster. In addition, the process provided information on the relative importance of tasks associated with the job situation. Finally, the process allowed for the field validation of existing DACUM charts and the identification of core competencies and modules for multi-level occupations. Using hunter training task statements, the study identified those tasks that cluster together by using a factor analytic approach. The clusters identified on the basis of field responses were the following: (1) identification and knowledge of species and their habitats; (2) survival; (3) knowledge and activities required in preparation for a hunting trip; (4) legal aspects of hunting; (5) safety; and (6) hunting ethics. In addition, information on the relative importance of all task items was extrapolated and interpreted with respect to implications for curriculum design and instruction as well as for the identification of core competencies and modules for complex work environments. ABSTRACT

Difficulties associated with the DACUM (Developing a Curriculum) process are identified in this study. A set of procedures are developed which can improve the process and to some extent overcome the difficulties associated with the process.

Essentially the study uses a collection of task statements generated out of a workshop situation, distributes these to the field for responses and then clusters these task statements on the basis of field responses. The clusters are then examined according to a behavioral taxonomy. This process allows for the identification of the physical and psychological requirements associated with a cluster.

In addition, the process provided information on the relative importance of tasks associated with the job situation.

Finally, the process allows for the field validation of existing DACUM charts and the identification of core competencies and modules for multi-level occupations.

Using Hunter training task statements, the study identifies those tasks that cluster together using a factor analytic approach. The clusters identified on the basis of field responses were:

- 1. Identification and knowledge of species and their habitats.
- 2. Survival.
- 3. Knowledge and activities required in preparation for a hunting trip.

- 4. Legal aspects of hunting.
- 5. Safety.
- 6. Hunting ethics. .

In addition, information on the relative importance of all task items
was extrapolated and interpreted with respect to implications for curriculum design and instruction.

Implications and further development of the procedures for the identification of core competencies and modules for complex work environments are discussed.

•

ERIC PROVIDENCE PROVID

In British Columbia, the DACUM (develop a curriculum) system of curriculum development has been used to make career training more effective. Presently, there are five steps involved in the DACUM process. The first two involve development of the curriculum through a cooperative effort between curriculum specialists and people working in the field. These steps are:

- 1. Conduct a job analysis.
- 2. Set performing objectives.
- Select evaluation instruments.
- 4. Choose instructional techniques.
- 5. Organize instructional resources.

To date, the job analysis process involved only task description. The data gathering strategy used was to conduct a workshop of ten to fifteen participants currently working in the occupation to be described. In addition, instructors in the occupational area were asked to participate as advisors and resource persons. The group was led by a workshop coordinator trained in the DACUM process. The workshop coordinator illicits a breakdown of tasks performed in the occupation under consideration.

As a starting point, the group identifies the job title and scope of the occupation. Then broad groupings of employee responsibility called the general areas of competence are listed. After these have been identified, the specific tasks within each broad grouping are identified. The job profile chart is the final product of this exercise. The tasks must be applicable to a broad variety of settings in the occupation because students are not being trained for just one company or work situation.

A final step in the process of job profile preparation is validation by a larger group of educators and practitioners.

After the job profile chart is complete performance objectives for each task are written. These materials are then provided to the course writer, curriculum specialists and instructors. The material forms the basis for planning instruction, organization of resource materials, teaching strategies and evaluation of performance.

There are some difficulties associated with the DACUM process as currently practiced. It is the purpose of this study to identify these areas and provide practitioners of the process with a set of procedures which can improve the process, and to some extent, overcome the difficulties and shortcomings of the process as now practiced. The utility and feasibility of this set of procedures are tested.

The difficulties associated with the DACUM process include the following:

a) The job analysis

The job analysis as practiced is only task description and not task analysis. Having effective means of collecting a body of task data and then classifying relevant aspects of it via a sound taxonomy is necessary for task description. Task description, however, is not sufficient by itself since one also requires a "behavioural understanding (that is, an analysis of the task requirements when viewed in both their physical and psychological settings" (Miller, 1963). Miller suggests that eventually measurement operations and other methodological tools for the elucidation of general factors and relationships that variables share with them are necessary to gain a more complete understanding of man-machine systems, (Miller 1962).

Finley et al (1970) also argue there has been a confusion between task description and task analysis. They state:

Although most researchers in the field have talked as if they wanted a taxonomy of task behaviour (i.e., a taxonomy describing the tasks presented to the personnel), - hence the term "task" analysis - in reality they have been looking for a taxonomy describing not tasks but the behaviour elicited by those tasks.

Fleishman (1967a, 1967b) has suggested that the goal in task analysis should be to identify the unifying dimensions underlying skilled behaviour.

Finley et al (1970) point out that the interpretation of task data:

must be based on behavioural dimensional analysis. What would be most desirable is a thorough analysis of the fundamental behavioural dimensions across all man-machine system tasks. (p.8)

b) The DACUM process presently does not elicit a list of tasks along a , dimension of underlying skilled behaviour.

The task descriptions are not examined according to a behavioural taxonomy to identify the physical and psychological requirements associated with a unified dimension of tasks. The process does not provide information regarding the relative importance of tasks within a dimension or area of general competence. The relative importance of general areas of competence are also not identified.

- c) The task descriptions presently are not extensively or methodologically validated.
- d) Core competencies are unable to be identified from task description alone.
- e) The process is presently unable to associate tasks to multi-level occupations, i.e. identify what tasks are carried out by what level and to what extent.

The Factor Analytic Approach

A statistical procedure which gives both qualitative and quantitative distinctions can be useful in the analysis of task statements. The procedure that aids in summarizing the interrelationships among a number of variables in a concise and accurate manner to aid in conceptualization is called factor analysis. The goal of factor analysis is to represent a large amount of data in an eacily comprehensible way by searching data for possible qualitative and quantitative distinctions.

This approach has been advocated in previous literature on task analysis (for example, Fournier, 1975; Prien and Ronan, 1971). Factor analytic methods can provide a systematic comprehensive approach to task analysis and provide information to overcome the deficiencies of the DACUM method.

In order to test the feasibility and practicality of the factor analytic approach a hunter training DACUM project was examined and subjected to an analysis of this type. It was planned to distribute task statements to a field of practitioners for validation of items and ascertaining relative importance of items. It was expected that after subjecting the resulting data to factor analysis that the task statements would be clustered in dimensions perceived by the field. It was hypothesized that these dimensions would be identifiable by both quantitative and qualitative means.

It was further hypothesized that an examination of the resulting dimensions would reveal that each dimension would contain a number of tasks associated with examples of specific performance types involving special cognitive processes. Finally, the analysis would provide information on the relative importance of each dimension and the relative importance of tasks within a dimension. These results would provide curriculum developers and instructors with concrete, useful information. It would assist the developer in categorizing the tasks in a meaningful, valid way, and aid in curriculum outlines and writing of curriculum. It would assist in allotting time and emphasis to the curricula. It would allow better presentation and resource allotment to the curriculum by the instructor and provide for a more meaningful evaluation of performance.

Procedure:

Tasks associated with hunter activities were first delineated as course objectives. This task was carried out by information and education officers from the Ministry of the Environment. A curriculum consultant took these objectives and translated them into task statements associated with the course objectives. In both these stages an effort was made to be as comprehensive as possible.

Questionnaire:

A questionnaire was designed using the task statements placed in random order with a five point importance scale attached. The anchors to the scale were very important to not at all important. A score of one was very important and a score of five was not at all important. This simple "Likert type" scale was similar to numerous scales of this type used in factor analytic work in personality and education, e.g. Boshier and Riddell (1978). A copy of the questionnaire and covering letter are provided in Appendix A. Questionnaires were sent to 1164 hunter training instructors.

Data Analysis:

The returned questionnaires were keypunched for computer analysis. The flow of analysis procedures are outlined in figure o.e. The theoretical analysis was deemed the desirable procedure. The factor analytic model that was used was a common factor analysis. It is assumed that the observed variable is influenced by various determinants some of which are shared by other variables in the set while others are not shared by any other variable. The part of a variable that is influenced by the shared determinants is usually called common, and the part that is influenced by idiosyncratic determinants is usually called unique. Under this assump-

tion, the unique part of a variable does not contribute to relationships among the variables. In addition, the observed correlations must be the result of the correlated variables sharing some of the common determinants. The common determinants will account for all the observed relations in the data and will be smaller in number than the variables. The variable domain are all program relevant items on the questionnaire: No marker variables exist because of lack of previous research in this area. It is, therefore, not known which key variables should be present on the various factors derived. It was not known exactly how many factors to expect a priori. Enough participants in the field were surveyed in order to yield a large enough ratio of respondents to items. Ideally, for stability of measurement with these procedures, five times as many individuals as items or variables is required. Because the aim of the procedure was an exploratory one to determine the number of clusters of task statements that would parsimoniously describe the data the sample was randomly split into two groups. Indices of association were calculated for each group. The number of nontrivial factors likely to be significant were determined on the basis of the following criteria.

- 1. A scree test to estimate "rubble" variance was computed.
- 2. Eigenvalues greater than one were examined from a principal component analysis.
- 3. Percent of variance accounted for was examined.
- 4. Loadings of items on factors were examined.

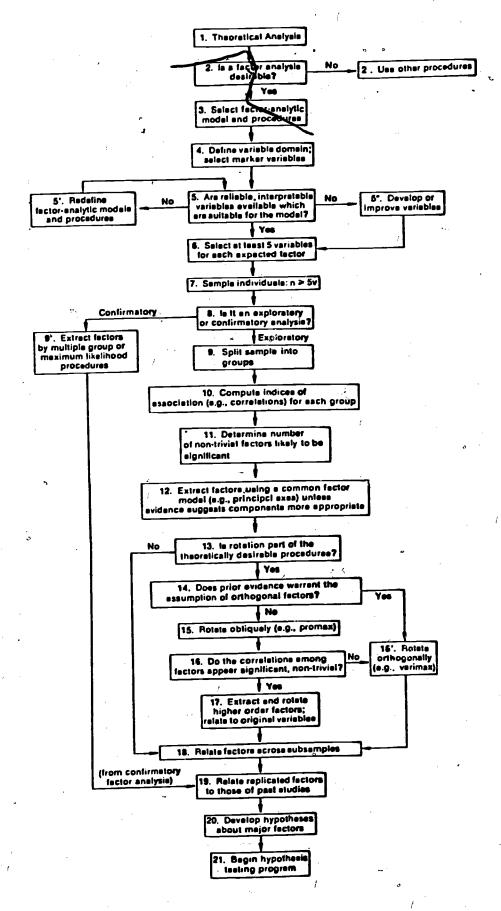

Factor analysis: Rao's Canonical Factoring was used. The factors derived are assumed to be determined by the linear combination of the common variance

portion of the observed variables. Estimation of communality or unique variance becomes the central problem. In addition, Rao's canonical factoring assumes that the given correlation matrix is based upon a sample of cases and asks what the most likely population parameters would be. Since sampling errors do exist it is expected that the resulting factor structure would not exactly fit the data. Factors were orthogonally rotated to varimax criterion in order to separate the factors as much as possible, that is an uncorrelated factor pattern was desired because higher order factors were not desired in this analysis. Factors derived were related across the two samples to check for stability. Internal consistency estimates for factors were calculated. Hypotheses about the major factors were generated. Implications for curriculum and instruction were derived.

Figure 1. Flow Chart of Analysis

RESULTS

Response Rate:

1164 questionnaires were sent out. 286 were returned and 131 were nondeliverable. This represented a response rate of 28%.

Data Analysis Results:

Appendix B presents frequency distributions and relevant statistics for each item of the questionnaire.

Table 1 presents means and standard deviations for each task statement in the curriculum area.

Table 2 presents the variable list (short form) with labels.

Table 3 presents the correlation Matrix for the entire 286 cases.

Table 4 presents communalities eigenvalues, percent of variance for the principal component estimates.

Table 5 presents the rotated factor pattern matrix with salient loadings identified.

Table 6 presents the DACUM derived from the factored field responses.

Table 7 presents the "intuitive" DACUM.

Demographics

An examination of the results indicated that for the entire group of respondents over two-thirds held a B.C. hunting license for over ten years.

64% of the respondents indicated they were members of an outdoor club sponsoring hunting but about 40% of the respondents indicated they were members of a club not sponsoring hunting. It appears that some respondents (about 4%) responded to both these items.

Most of the respondents (34.6%) were in the 31 to 40 years age group. About half of the respondents were over 30 years of age.

Indices of Association

An examination of the means and standard deviations of the two halves of the sample on task statements revealed a high degree of similarity. A correlation matrix of task statements was generated for each of the split half samples. For the most part correlations were very similar across the samples. The frequency printout of variables distributions confirmed that the assumption of multivariate normality was reasonable and factoring could be carried out.

Relative Importance of Items

Because very high importance was rated a 1 and low importance was rated a 5 the lowest mean rating would represent very high importance on a task. An arbitrary division of items on the relative importance scale would result

in the following:

Items considered most important

(rating 1.0 to 1.4)

- . demonstrating safe handling of firearms.
- . identifying safe discharge of firearms.
- . ten commandments of firearm safety.
- . identify survival first aid procedures.
- . demonstrate safe discharge of firearms.
- . identify safe game targets.
- . define hunter ethics.
- . identify legal and non-legal species.
- . identify positive attitudes to outdoor survival.
- . define outdoor ethics.
- . components of outdoor survival.
- . treatment of hypothermia.

Each of the above task statements were considered to be very important elements in hunter training. The items listed above also exhibited standard deviations less than 1.0 indicating a high consensus among the respondees on the ratings of these items.

Items considered important

(Ratings 1.5 to 2.00)

- . Identify seven enemies of survival.
- . identify protected-endangered birds.
- . procedures helping injured persons.
- . identify protected mammals of B.C.
- . identify special licenses required.

- . obtain hunting regulations and acts.
- . select firearm and ammunition for game.
- . define terms used in regulations.
- . zone restrictions and bag limits.
- . identify and classify firearms.
- . regulations and principles of wild life management.
- . reporting unacceptable behaviour.
- . identify characteristics of manual species.

These items are considered to be important but the results indicate that they are less important relatively speaking than the group rated 1.0 to 1.4 above. An examination of the standard deviation of these items indicate the standard deviations to be around one unit. This indicates a somewhat greater diversity in the rating of these items.

Items on the <u>lower end of the importance dimension</u> include the following. (rating above 2.0).

- . field dressing for animals.
- . dismantle and clean firearm.
- . identify habits and distribution of game birds.
- . habitat distribution individual species.
- . define common mammal terms.
- . identify effect of man on birds.
- . identify procedures for buying firearms.
- . apply keys to identification of birds.
- . identify and name game birds of B.C.
- . define bird related terms.
- ./basic principles of ballistics and trajectory.

- . define regulations field dressing.
- . make-up survival kit.
- . list equipment for field trip.
- . practice components of outdoor survival.
- . effect of man on mammals.
- . list preparations for hunting trip.
- . apply key identification of mammals.
- . identify firearm parts.

These items are listed as having a lower level of importance. The standard deviations on these items are usually greater than one indicating less consensus and more variability of response in the rating of these items on the importance dimension.

The results of the correlation analysis produced a 45 by 45 item matrix the principal component analysis yielded 45 eigenvalues that were subjected to a "scree" test (Cattel, 1966) the results were not unequivocal but this test and the use of other criteria (e.g. Guttman's 1954 lower bound for estimating the number of factors and significant variance unaccounted for) indicated that 6 factors appeared reasonable. A 6 factor solution accounted for approximately 57% of the total variance.

Results of the Factor Analysis

The 6 factor solution identified the clusters of variables that conceptually belong together. The items that have salient loadings on the first factor are concerned with the identification and knowledge of species and their habitats. The items loading very high on this dimension are:

- . defining bird related terms.
- . habitat distribution individual species.
- . define common mammal terms.
- . identify habitats distribution of game birds.
- . apply keys to identification of birds.
- . identify effect of man on birds.
- . effect of man on mammals.
- . identify and name gamebirds of B.C.
- . apply key identification of mammals.

The cognitive process that permeate the tasks in this dimension are related to perceptual activities and mediational activities. The performance associated with these processes are:

- a. searching for and receiving information.
- b. identifying objects, actions and events.
- c. information processing.

Under a. the examples of behaviour are mainly observation.

Under b. the examples of behaviour are locating, discriminating and identification.

Under c. the examples of behaviour are categorization and itemization.

As a consequence the curriculum could be organized to include these tasks in one unit. The curriculum and instruction would require a variety of visual aides, discrimination and identification tasks and test questions concerned with

identification of species and their categorization. The relatively low importance these items were rated indicates that the evaluation of the performance may not need to set stringent criteria, i.e. the pass/fail cut-off point can be lower than on other areas of curriculum knowledge.

The items loading on the second factor pertain to <u>survival</u>. Task statements that loaded high on this dimension are:

- . identify components of outdoor survival.
- . identify procedures for treatment of hypothermia.
- . procedures helping injured person.
- . identify seven enemies of survival.
- . make-up survival kit.
- . identify positive attitudes for outdoor survival.
- . identify survival first aid procedures.

The cognitive processes that permeate the tasks in this dimension are perceptual, mediational, communication and motor. The associated performance types under the perceptual process are searching for and receiving information and identifying objects, actions, events. The specific examples of behaviour include detection, inspection, observation, scanning and survey activities. Other perceptual process behaviours in this group include identification, discrimination and locating.

The mediational process involves performance types of information processing, problem solving and decision-making. The specific behaviours include categorizing, itemizing, translating, analyzing, comparing, estimating, choosing and planning. The communication process involved in this dimension include behaviours of advising, answering, directing, informing, instructing, transmitting and requesting.

The motor process involves use of both simple and complex performance and includes behaviour of activating, closing, connecting, moving, pressing, joining, setting, adjusting, tracking and regulating.

The relative importance rating of these activities indicates that the evaluation of the performance would require a high degree of proficiency to be required. The criterian should be fairly stringent and the pass/fail cut-off should be set fairly high relative to other curriculum areas.

The third factor has task statements associated with knowledge and activities required in preparation for a hunting trip. The items with salient loadings on this factor are:

- . list preparations for hunting trip.
- . list equipment for field trip.
- . obtain hunting regulations and acts.
- . describing basic principles of ballistics and trajectory.
- . list procedures for safe, efficient field dressing for animals.
- . define regulations that apply to field dressing.
- . identify procedures for observing, recording and reporting unacceptable behaviour.

The cognitive processes that permeate this dimension involves mediational and motor processes. The performance types associated with the mediational process include information processing, problem-solving and decision-making. The performance type associated with the motor process is simple/discrete tasks and complex/continuous tasks. The specific examples of behaviours for the mediational process is itemizing, analyzing, choosing, estimating, planning. The specific examples for the motor process is

setting, pressing, moving, activating, adjusting, aligning, and tracking. The relatively low importance attached to most of the activities associated with this dimension would prescribe that the evaluation of performance does not require a high degree of proficiency and criteria for evaluation do not need to be stringent. The pass/fail cut-off could be set fairly low relative to other curriculum areas.

Factor 4 has tasks associated with <u>legal aspects of hunting</u>. The items with salient loadings on this factor are:

- . identification of protected mammals of B.C.
- . identify protected endangered birds.
- . zone restrictions and bag limits.
- . identify special licenses required.
- . identify safe game targets.*

*This item could be interpreted as "permissable" game targets or as a "safe" target. The positioning on a factor would have depended upon interpretation by the field and therefore was not a clearly worded item.

This factor involves the perceptual and mediational processes. The performance types involve with perception are searching for and receiving information and identification of objects. The performance types associated with the mediational process are information processing and decision making. The specific examples of behaviour for the perceptual mode are observing, detecting, surveying, reading and scanning, discriminating, identification and locating. The specific examples of behaviour of the mediational process involve categorization, coding, itemizing, translating, analyzing, comparing and choosing.

The items loading on this dimension are provided with importance ratings that fall in the area of high importance. The average rating on these items are about 1.5 indicating a high importance attached to these functions. Instructors should make students well aware of these tasks and how to obtain information in connection with them. Criteria for performance evaluation should be high.

The fifth factor has task statements associated with safety loading on it.

This "factor" has only three items loading on it:

- . identification of safe discharge of firearms.
- . demonstrate safe handling of firearms.
- . list ten commandments of firearm safety.

The cognitive processes involved with the tasks on this factor are perceptual, mediational, communication and motor. The performance types associated with these are:

>

Perceptual

- . identification, inspection, observing.
- . locates.

Communication

. communicating, answers, advises, informs, indicates, instructs, requests and transmits.

Motor

. activates, closes, connects, moves, joins, disconnects, presses/sets, adjusts/aligns, synchronizes and tracks.

The high importance attached to the items on this factor indicate that a great deal of care and attention should be given to their instruction. The tasks loading on this dimension require checking, fine adjusting and if not carried out correctly can lead to disastrous consequences. These tasks require stringent criteria for pass/fail and should involve a great deal of practice elements.

The final factor has only two loadings that are salient. These are associated with hunting ethics:

- . define hunter ethics.
- . define outdoor ethics.

Both these items involve the mediational process and the performance type is information processing, problem solving and decision making. The specific examples of behaviour include categorization, translating, choosing, comparing, estimating and planning.

It is clear that the fifth and pecially the sixth "factor" do not have enough items to measure reliably and would require a few more items to become replicable factors. These shortcomings are a reflection of the questionnaires and the workshop process in that these two domains could be mapped out in a more comprehensive manner. It is possible for workshop participants to generate rore safety statements with regard to firearm handling and more statements on hunter ethics.

DISCUSSION

The use of a multivariate technique like factor analysis can provide useful information in the area of task analysis. The need for such a technique is readily appreciated when there are a large number of task statements and both qualitative and quantitative information is desired. In addition, the original set of statements can be reduced to a much smaller set which accounts for most of the reliable variance of the initial pool of task statements. This smaller set can then be used as operational representatives underlying the complete set of variables. If the domain of data can be hypothesized to have certain qualitative and quantitative distinctions, then this hypothesis can be tested by factor analysis. If the hypotheses are tenable, the various factors will represent the theoretically derived qualitative distinctions. If one variable is hypothesized to be more related to one factor than another this quantitative distinction can also be checked.

Other statistical procedures such as simple product-moment correlation of task statements with levels of job could yield valuable information regarding "core" tasks carried out throughout and specialized "modules" of tasks for certain job levels.

The use of the multivariate approach is necessary because where there are numerous variables it is difficult to examine any matrix of association indices for "intuitive" factors. The task simply becomes too great. The number of indices of association between each pair of variables in a set is equal to V(V-1)/2 where V is the number of variables. For example, a 50 variable problem would have 1,225 coefficients. Most of us find some difficulty in integrating 1,225 interrelationships by an intuitive analysis.

The purpose of this study was to use a factor analytic approach to analyse task data and validate a DACUM. The field-developed DACUM differed somewhat from the factors intuitively derived. In addition, it provided more information for curriculum development and instruction than the intuitive approach.

A major contribution of the present survey methodology is the identification of "core" competencies and specialized modules as practiced in the field. Using correlations between level of job categories and rating distributions on individual task statements it is possible to identify those tasks practiced by all and those unique to individual levels. In the simplest case, a two level category, e.g. administrator and practitioner, a non-significant correlation between this dichotomous grouping and a particular task would indicate that the task was carried out by both administrators and practitioners and would be a candidate for the "core" task statements. Assume the rating scales were 1= not at all important and 5= most important and the administrator was assigned a value of 2 and practitioner a 1. A significant positive correlation would indicate that task statement to be primarily important to administrators. In a similar way a significant negative correlation would indicate that task statement to be primarily associated with the practitioner. This procedure is a highly efficient way to obtain both reliable and valid data for the identification of specialized modules and "core" elements.

The use of other scales in conjunction with importance would also yield valuable curriculum design information. Some specific dimensions in

addition to importance which would be valuable to obtain responses on could be frequency, mental effort, manual dexterity and speed.

Assumptions and Limitations

- 1. The procedure assumes a linear model, i.e. some variables often called dependent variables or criteria are assumed to be a weighted combination of a set of factors. If non-linear relationships are involved no analysis within the linear model is truly adequate. However, if a non-linear relationship is expected the variable might be transformed so that the relationship between the derived variable and the factors is linear, Bottenberg and Ward, 1963, Kelly, Beggs and McNeil, 1969.
- 2°. Responses from the field should be large enough to carry out the analysis. A ratio of five respondents to one item is desirable from a stability viewpoint. In addition, if it is essential that the findings are generalizable across geographic areas an examination of the adequacy of sampling in geographic areas would be required.
- 3. Only the importance dimension was examined and certain tasks may be very unimportant but done frequently or vice versa. This information is lost or not available when only an importance scale is used. Similarly, other scales could provide salient findings that an importance scale alone would not tap.
- 4. Hunter training in this study was not a multi-level occupation and thus identification of core and modules for levels was not necessary.

5. Items 5, 6, 7 and 8 of the demographics were not keypunched due to error in keypunching instructions and are not presented in this report.

Comparison and Implications

A comparison of the workshop produced DACUM and field-produced DACUM charts indicate a few areas of difference.

- 1. The identification of Birds and Mammals were separated out in the workshop DACUM as two distinct clusters. However, the field analysis indicates that one cluster containing both mammals and birds is more appropriate. This is due to these task statements correlating well, primarily because of similar variances on the importance ratings. The psychological processes involved in the identification of species is similar for both birds and mammals. The workshop differentiation into birds and mammals was an artificial partitioning based on classification of species rather than on actual cognitive requirements.
- "clean". In contrast to the clear distinction
 based on classification only between bird and animal clusters,
 there are a number of combination factors that seem to combine
 elements that essentially are unrelated. An example is the
 cluster "plan safe ethical field trips". A close examination of
 this cluster reveals items somewhat unrelated, e.g., defining
 hunter ethics, listing preparations for hunting trip, making up
 a survival kit and listing procedures for safe efficient field
 dressing for animals. Clearly on content alone some of these
 items would more appropriately belong to a survival or first aid
 cluster or to preparations for a hunting trip cluster.

The reason for these poor juxtapositioning of task statements is an inherent human inability to conceptually deal with the many interrelated task elements. This inability combined with the lack of a broad enough information base that is field oriented results in suboptimal delineation of clusters and organization of curriculum.

These shortcomings can be easily overcome with the present technology.

Not only is the process extremely inexpensive and relatively quick
but it accomplishes a number of critical issues:

- 1. Optimizes the number of clusters of task statements.
- 2. Assigns task statements to clusters on a rational and optimal basis.
- Field validates the DACUM chart.
- 4. Provides information on relative importance or other dimensions of task items.
- 5. Aids in the assignment of a taxonomic approach to task analysis.
- 6. Delineates "core" and modules in a valid way.
- Allows for industry and field input into the curriculum process.
- 8. Is especially suitable in highly technical areas where certain task elements are critical to success.

The benefits of these considerations are several. The first is cost.

Costs would be substantially reduced. The workshop situation could be substantially reduced to generating initial task statements. Indeed, if other territories already have existing skill profile charts, the workshops are redundant and it is simply a matter to determine how each of the existing elements relate in B.C. and what differences there may be. Keypunching and computer services costs are negligible. The factor analytic run in this study cost about \$4.00.

Time: Questionnaire preparation would take one to two days. Mailout and return mail responses would take about one month. Keypunching and data analysis about one week. Final chart preparation about one day.

Total actual work time - about two weeks.

Curriculum and Instructor Time economies would result from the identification of relatively important tasks.

The learning process would be enhanced because of the organization resulting from the analysis.

Field participation enhances the credibility of the finished product.

It is both up-to-date and valid. The quality of graduate is enhanced.
